APPLICATION FOR U.S. PATENT UNDER 37 C.F.R. § 1.53(b) TRANSMITTAL FORM

Box Patent Application ASSISTANT COMMISSIONER FOR PATENTS Washington, D.C. 20231

Sir:

Transmitted herewith for filing is the patent application of:

Inventor: Keith A. Lowery, et al.

Entitled:

METHOD AND APPARATUS FOR DYNAMIC DATA FLOW CONTROL

Enclosed are:

X Specification (84 Total Pages)

X Drawing(s) (4 Total Sheet(s) of X Formal Informal)

X Combined Declaration and Power of Attorney (5 Total Pages)

X Newly executed (original or copy)

Copy from a prior application (for continuation/divisional only)

X An Assignment of the invention to epicRealm, Inc. is attached.

A separate cover sheet in compliance with 37 C.F.R. § 3.28 and § 3.31 is included with an Assignment recordal fee of \$40.00 pursuant to 37 C.F.R. § 1.21(h).

X Certificate of Mailing

X Return Receipt Postcard

X Other This application claims the benefit of U.S. Provisional Application No.

60/180,587 filed February 7, 2000.

Express Mail Receipt No. EL501043607US

Applicant is:

METHOD AND APPARATUS FOR DYNAMIC

DATA FLOW CONTROL

BOX PATENT APPLICATION

Honorable Assistant Commissioner For Patents Washington, D.C. 20231

Dear Sir:

<u>iomoutes runatu</u>

CERTIFICATE OF MAILING BY EXPRESS MAIL

I hereby certify that the attached Patent Application (84 pages), Declaration and Power of Attorney (5 pages), Formal Drawings (4 pages), a check in the amount of \$672.00, Assignment (2 pages), Assignment Cover Sheet (2 pages), a check in the amount of \$40.00, Filing Fee Transmittal (2 pages), Verified Statement Claiming Small Entity Status (1 page) and this Certificate of Mailing are being deposited with the United States Postal Service "Express Mail Post Office to Addressee" service under 37 C.F.R. § 1.10 on this 8th day of June, 2000 and is addressed to the Assistant Commissioner for Patents, Washington, D.C. 20231.

Willie Jiles

Express Mail Receipt No. EL501043607US Attorney's Docket No.: 066241.0105 Applicant or Patentee: Keith A. Lowery, et al. Attorney's Docket No.: 066241.0105

Title: METHOD AND APPARATUS FOR DYNAMIC DATA FLOW CONTROL

VERIFIED STATEMENT (DECLARATION) CLAIMING SMALL ENTITY STATUS (37 CFR 1.9(f) & 1.27(c)) -- SMALL BUSINESS CONCERN

I hereby declare that I am an official of the small business concern empowered to act on behalf of the concern identified below:

Name of Small Business Concern:

epicRealm, Inc.

Address of Small Business Concern:

1651 N. Glenville Drive, Suite 212, Richardson, Texas 75081

I hereby declare that the above-identified small business concern qualifies as a small business concern as defined in 13 CFR 121.12, and reproduced in 37 CFR 1.9(d), for purposes of paying reduced fees to the United States Patent and Trademark Office, in that the number of employees of the concern, including those of its affiliates, does not exceed 500 persons. For purposes of this statement, (1) the number of employees of the business concern is the average over the previous fiscal year of the concern of the persons employed on a full-time, part-time or temporary basis during each of the pay periods of the fiscal year, and (2) concerns are affiliates of each other when either, directly or indirectly, one concern controls or has the power to control both.

I hereby declare that rights under contract or law have been conveyed to and remain with the small business concern identified above with regard to the invention, entitled *METHOD AND APPARATUS FOR DYNAMIC DATA FLOW CONTROL* by inventor(s) Keith A. Lowery, David K. Davidson, and Avinash C. Saxena, described in the specification filed herewith.

If the rights held by the above-identified small business concern are not exclusive, each individual, concern or organization having rights in the invention is listed below, and no rights to the invention are held by any person, other than the inventor, who would not qualify as an independent inventor under 37 CFR 1.9(c) if that person made the invention, or by any concern which would not qualify as a small business concern under 37 CFR 1.9(d), or a nonprofit organization under 37 CFR 1.9(e):

NONE

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or my maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 CFR 1.28(b)).

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this verified statement is directed.

Name of Person Signing:
Title of Person if other than owner
Address of Person Signing:

Bradley A. Carl Vice President and General Counsel 1651 N. Glenville Drive, Suite 212, Richardson, Texas 75081

METHOD AND APPARATUS FOR DYNAMIC DATA FLOW CONTROL

RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application Serial No. 60/180,587, filed February 7, 2000 by Keith A. Lowery, et al., attorney's docket number 066241.0105, and entitled, "Method and Apparatus for Dynamic Data Flow Control".

10

5

TECHNICAL FIELD OF THE INVENTION

This invention relates in general to client-server systems and, more particularly, to a method and apparatus for dynamic data flow control.

15

20

25

30

BACKGROUND OF THE INVENTION

As computers have grown increasingly important in today's society, the importance of the Internet has also increased. As increased numbers of users access the Internet, the need for a web server to handle large numbers of data requests has also increased. In addition, as increasing numbers of requests are handled by the Internet, the delay experienced by the user between generating the request and receiving a response is also increasing.

Some traditional solutions to handling large numbers of data requests and decreasing the delay at the web server have involved increasing the processing capability of the web server and distributing the processing of the requests across Other traditional solutions have groups of web servers. involved increasing the bandwidth of the network connection between the Internet and the web server or servers. However, traditional solutions have often failed as the number of of the continue to increase because associated with maintaining large numbers of web servers and high speed connections to the Internet.

Electronic commerce often involves large amounts of different types of data. Similar to traditional brick and mortar stores, different people have different values to the retailer. For example, customers who are purchasing items at a check-out counter typically receive faster service than customer who are simply browsing since the store knows that the purchasing customer will be spending money while the browsing customer who may not purchase anything. Also, regular customers are often known to the sales staff and receive faster and more personalized service. Traditional electronic commerce systems have often failed similar levels

of provide faster and more personalized service to different electronic commerce customers.

10

20

25

30

SUMMARY OF THE INVENTION

From the foregoing, it may be appreciated that a need has arisen for a method and apparatus for dynamic data flow control so as to provide increased efficiency for handling large numbers of requests by a web site.

According to one embodiment of the present invention, a method for data processing is provided which comprises receiving a data request at a data center. The method further comprises assigning a priority to the request. Also, the method comprises queuing the request as a function of the priority associated with the request and retrieving the requested data from an origin server.

According to another embodiment of the present invention, a system for dynamic flow control is provided which comprises a cache server operable to receive a request for content and retrieve content from an origin server in response thereto and a flow control server having an associated queue and coupled to the cache server. The flow control server is operable to determine assign a priority to the request. The flow control server is also operable to store the prioritized request in the queue as a function of the priority associated with the request and regulate the retrieval of content from the origin server by the cache server.

The present invention provides a number of technical advantages. One such technical advantage is the capability to prioritize requests based on a request and an origin server to which the request is addressed for controlling the processing load at the origin server. Another such technical advantage is the capability to configure a data center for independent control of the processing load experienced by different origin servers. A further technical advantage is the capability to provide status information about the request to a user

Comositos et comon

associated with the request based on the delay in processing the request and other configurable criteria associated with the origin server.

15

BRIEF DESCRIPTION OF THE DRAWINGS

A better understanding of the present invention will be realized from the detailed description that follows, taken in conjunction with the accompanying drawings, in which:

5 FIGURE 1 is a block diagram of a web content caching system;

FIGURE 2 is an exemplary network illustrating network distance between a source node and a destination node;

FIGURE 3 is block diagram illustrating details of the web content caching system of FIGURE 1;

FIGURE 4 is a block diagram illustrating details of a flow control server usable with the present invention;

FIGURE 5 is a block diagram illustrating details of a cache server system usable with the present invention; and

FIGURE 6 is a flowchart illustrating the data caching and dynamic flow control method of the web content caching system of FIGURE 1.

10

15

20

25

30

DETAILED DESCRIPTION OF THE INVENTION

FIGURE 1 is a block diagram of a web content caching system 10. Caching system 10 comprises a plurality of clients 11, a browser 12 executing on client 11, a network 13, one or more data centers 14, a data center manager 16, an origin server 18, a data source 20 and a Domain Name Service (DNS) server 23. Caching system 10 provides increased World Wide ("web") performance to clients 11. Performance is increased by caching data at the data centers 14 so that the data is located closer, in terms of network distance, to the clients 11, by decreasing the volume of data requests handled by origin server 18 and by decreasing the volume of dynamic data to be generated by origin server 18. It should be understood that while the disclosed embodiment is discussed in terms of the Internet Protocol (IP), any suitable network protocol could be used, such as Asynchronous Transfer Mode (ATM), frame relay and Fiber Distributed Data Interface (FDDI).

Each client 11 comprises any suitable general purpose or specialized computer system operable to support execution of browser 12. Clients 11 respectively comprise a processor 15 and a computer readable memory 17 coupled to processor 15. Each client 11 is coupled to network 13. Browser 12 executes on client 11 and comprises any suitable Hypertext Transport Protocol (HTTP) client. In the disclosed embodiment, browser 12 comprises a web browser such as Internet Explorer® by Microsoft Corp. of Redmond, Washington orNetscape Communicator by Netscape Communications Corp. Browser 12 is held in memory 17 and executed by processor 15. Browser 12 transmits and receives data over network 13. Each browser 12 is operable to generate one or more requests 22. Each request 22 is generated by a particular browser 12 in response to a TOUGHT TOUGHT

10

15

20

25

30

desire for information by a user (not shown) associated with that particular browser 12. Each request 22 comprises a request for one item of content from origin server 18. requested item of content may further comprises multiple elements of content, for example, a web page with multiple graphic elements therein, but the request is directed to retrieving the single content item while the elements of content in the main content item are retrieved as a function of the single content item. Content video data, static and dynamic audio data, text multimedia data, Hypertext Markup Language (HTML) data, binary data and any other suitable types of data capable of being used by browser 12. In the disclosed embodiment, requests 22 are HTTP requests for HTML data, such as web pages. of content ("content item") indicates a particular element of content, such as a particular web page, while content refers generally to data available to be retrieved.

comprises static information and dynamic Content information. Static information typically does not change once the content has been created or does not change except Stated another way, static information slowly over time. comprises content that, when created, is expected to remain same for an indeterminate amount of time. the information may comprise, for example, text files and preexisting Hypertext Markup Language (HTML) web pages. example, a restaurant menu is the same regardless of the user who is accessing the menu because the menu is the same for all However, as chefs at the restaurant change over time, the menu may also change. In contrast, dynamic information comprises content that is expected and designed to change. The dynamic content may change based on the data and criteria used for generating the dynamic content, such as a search

10

15

20

25

30

result page. For example, a search for "mountain lions" will listing items dynamically generate a search result page related to "mountain lions." The dynamic content may also change based on information associated with the page, for example, a page in an online product catalog may change in response to pricing and availability changes, and dynamic for other suitable further change content may Dynamic information may comprise, for example, the output of Common Gateway Interface (CGI) scripts, search engine results, the output of Structured Query Language (SQL) searches and the SOL search itself, JavaScript, the output of JavaScript scripts, ActiveX controls and the output of ActiveX controls, Active Server Pages, applets and any other suitable dynamic Often, the dynamic information content generation system. be expressed as a single HTML web page, information within the HTML web page has been generated dynamically based on some suitable criteria. For example, the result of a search using a search engine on the Internet different information based the search returns on provided by the user. The search results may also depend on one or more attributes associated with the search request, such as geographic location or the current date. Continuing the search engine example, when the user is searching for local businesses, the search results will vary not only on the search terms provided by the user, but also what "local" means with respect to the search request . For another example, a user searching for information about current events will want results that are tailored to the user's search terms, the user's location. and the current date. For yet example, an online book retailer may provide price information and consumer reviews of books available from the online book retailer. The price information for a particular book may

10

15

20

25

30

change unexpectedly in response to a sale or a sudden interest in that particular book. Also, the web page listing the book and the consumer reviews changes in response to a consumer entering a new review of the book. One aspect of the system of the present invention allows for the efficient caching of static information that never changes, static information, such as the menu example, that changes infrequently, and some suitable types of dynamic information.

Network 13 comprises any suitable data networking system for communicating data between computer systems. For example, network 13 may be the Internet, an asynchronous transfer mode ("ATM") network, an Ethernet network, a Transmission Control Protocol/Internet Protocol (TCP/IP) network, an intranet or any other suitable computer networking technologies. For purposes of teaching the present invention, an exemplary embodiment will be described where network 13 comprises the Internet.

Data centers 14 cache content for transmission 22. Data center 14 12 in response to requests to request 22 from browser 12 by providing the requested web page or other data to browser 12 using network Data centers 14 are described in more detail 13. association with FIGURE 3. In the disclosed embodiment, data centers 14 cache content from origin server 18. Data centers 14 provide current, cached content originally available from origin server 18 to a browser 12 in response to request 22. In the disclosed embodiment, data centers 14 are shown as communicating with a single exemplary origin server however, data centers 14 are operable to communicate with and provide service to a plurality of origin servers 18.

Caching content comprises storing a copy of content available at or generated by origin server 18. Content is

10

15

20

25

30

initially generated at origin server 18 and a copy is stored ("cached") at data centers 14. The copy is retrieved by a particular data center 14, such as data center 14A, in response to receiving a particular request 22 requesting particular content. If that particular content is not available at data center 14A, then that particular content is retrieved from origin server 18. The caching process is described in more detail in association with FIGURE 5. A copy of the content available from origin server 18 may be stored at one particular data center 14, a plurality of the data centers 14 or all of the data centers 14 depending on which data centers 14 receive requests 22 for that content.

As discussed previously, some content may be dynamic in the sense that it may become inaccurate or superceded over time. To address this situation, content currently existing at the data centers 14 may be marked as expired in response to an expiration command 24 (discussed in detail in association with FIGURE 5) from data center manager 16. Content may alternatively be actively deleted in response to expiration command 24. Expired content is considered locally unavailable at data centers 14 by data centers 14 and is retrieved from origin server 18 in response to a new request 22 for the particular content.

Caching content at data centers 14 decreases the number of requests 22 that must be serviced by origin server 18. In the disclosed embodiment, since data centers 14 will request content from origin server 18 only when the content is locally unavailable at data center 14, origin server 18 will be required to generate or provide a particular content item a maximum number of times. Typically, the maximum number of content generation occurrences equals the total number of data centers; however, the number of content generation occurrences

10

20

25

30

may exceed the total number of data centers. For example, if 10 data centers are used, then the origin server will only have to generate a particular content item at most 10 times, once for each data center, because after the particular content item is generated for each data center 14, the data centers 14 will provide the particular content item to browser 12 instead of origin server 18 providing the content item to browser 12. By spreading requests 22 over a plurality of data centers 14, response time is decreased because the processing load associated with servicing the requests is spread over multiple computers at multiple locations. Also. disclosed embodiment, data centers 14 are located closer, in terms of network distance, to clients 11. Network distance is described in more detail in association with FIGURE example, data center 14A is closer to client 11A, data center 14B is closer to client 11B, and data center 14C is closer to However, any data center 14A-C may service requests from browser 12 on any client 11A-C. Locating data centers 14 closer to clients 11 decreases the response time for handling requests by decreasing the amount of time that the response and the request spends in transit over network 13 from a particular data center 14 to a particular client 11.

Data center manager 16 is coupled to data source 20 and data centers 14. Data center manager 16 operates to expire content at data centers 14. In the disclosed embodiment, data center manager 16 comprises a computer system executing software which is operable to expire content at data centers 14. Data center manager 16 expires content at data centers 14 by sending data expiration commands 24 to data centers 14. Data center manager 16 may generate data expiration command 24, for example, in response to a change in the content at data source 20. Specifically, data center manager 16

10

15

20

25

30

generates data expiration command 24 in response to a data change message 28 (discussed in more detail in association with FIGURE 5) from data source 20. Data center manager 16 may also generate data expiration command 24 in response to the elapsing of a predetermined time period. For example, data center 16 may know that certain content changes at periodic intervals at data source 20 and independently generates a data expiration command 24 for that content.

Data source 20 stores data used for generating content and content itself. Data source 20 comprises magnetic storage devices, optical storage devices, persistent storage devices, transient storage devices, and any other suitable storage device or technology for storing data. Data source 20 may be a portion of origin server 18 or may be physically separate therefrom. Data source 20 includes a trigger portion 21. Trigger portion 21 of data source 20 generates data change message 28 indicating changes in the content or portions of content available from origin server 18 and stored in data source 20. Trigger portion 21 may also indicate a change in the data based on the time and date. Data change message 28 is then communicated to data center manager 16.

Origin server 18 is coupled to data centers 14 and data source 20. Origin server 18 comprises software executing on a computer for receiving and responding to requests 22. Origin server 18 may comprise a single computer executing software or may comprise a plurality of computers each executing software. In the disclosed embodiment, origin server 18 is associated with a single Internet domain; however, multiple origin servers 18 associated with multiple distinct Internet domains are also usable in connection with the present invention. Also, in the disclosed embodiment, origin server 18 is a hypertext transport protocol (HTTP) server which is also known

15

as a web server. Origin server 18 may additionally support other protocols such as the file transfer protocol (FTP) and the gopher protocol. Origin server 18 retrieves information from data source 20 in response to requests 22 forwarded from data centers 14. Origin server 18 is operable to retrieve static content, such as prewritten text files, images, and web pages, from data source 20 in response to requests 22. Origin server 18 is also operable to generate new, dynamic content, by dynamically creating web pages based example, content stored in data source 20 in response to requests 22. For example, origin server 18 may generate a new web page using a common gateway interface (CGI) script, generate a new web page from the result of a structured query language (SQL) perform other suitable content generation request and Origin server 18 may also be operable to generate executable software, such as applications and applets, response to requests for data. For example, origin server 18 may generate a Java applet in response to an appropriate request 22.

DNS server 23 comprises any suitable DNS server 20 translating machine and domain names into numeric Internet Protocol (IP) addresses. DNS server 23 may also comprise a single DNS server or multiple DNS servers; however, DNS server 23 is discussed as if it were a single DNS server. 25 for origin server 18 to be served by data centers 14, DNS server 23 resolves machine and domain names associated with origin server 18 to data centers 14. Specifically, all or a portion of the domain names and machine names associated with origin server 18 are translated to IP addresses associated 30 with data centers 14. Requests 22 directed to origin server 18 will now be received by data centers 14 from browsers 12 before requests 22 reach origin server 18. Specifically,

15

20

25

30

requests 22 directed to domain names and machine names associated with origin server 18 resolve to IP addresses data centers 14. Any subset of the domain names and machine names in any suitable combination may be redirected to data centers 14. The subset can be changed by the administrator associated with origin server 18 at any time so as to provide flexibility as to whether content at origin server 18 is cached. Data centers 14 can then control the flow of requests 22 between browsers 12 and origin server 18.

operation, browsers 12 generate requests for content from origin server 18. One of the data centers 14 receives request 22. Data centers 14 receive request 22 even though request 22 is directed at origin server 18 because DNS resolution has directed request 22 to data center 14. Stated another way, requests 22 addressed to origin server 18 are routed to data centers 14. For example, if browser 12 on client 11A generates request 22, then data center 14A receives 22 before request 22 reaches origin server Specifically, request 22 has an associated address portion indicating the destination web site for request 22. Since DNS server 23 resolves one of data centers 14 as the destination instead of origin server 18, data centers 14 can receive request 22 by resolving the address portion of request 22 to the address of the closest, in network distance, data center 14 to browser 12 using DNS server 23.

Continuing the above example, data center 14A then determines whether the requested content has been cached at data center 14A. If the requested content is cached at data center 14A, then request 22 is handled at data center 14A and the requested content is returned to browser 12. If the requested content is not available at data center 14A, request 22 is forwarded to origin server 18 for handling. When origin

10

15

20

25

30

server 18 is required to handle request 22, the requested content will first be communicated to data center 14A for caching, if the requested content is to be cached, and then transmitted from data center 14A to browser 12 on client 11A.

FIGURE 2 is an exemplary network illustrating network distance between a source node 50 and a destination node 52 in a packet switched network. Source node 50 comprises any suitable network device, such as a computer, operable to generate a data packet for communication to destination node Destination node 52 comprises any suitable network device for receiving data packets from source node 50, such as a computer. Between source and destination nodes 50 and 52 is a communication network 53 such as the Internet. Communications network 53 comprises a plurality of nodes 54, 56, 58, 60, and Each node 54, 56, 58, 60 and 62 comprises any suitable network device for receiving data packets and transmitting data packets, such as a computer or router. Each of the nodes 50, 52, 54, 56, 58, 60 and 62 are coupled by communications links 64. Each of the communications links 64 has a latency associated therewith. The latency represents the sum of the time a packet has spent waiting to be forwarded out of a particular node and the transit time over the link, convenience, the latency is associated with a particular link, even though a majority of the latency time will typically be spent by the packet while waiting to be forwarded out of the The latency is indicated by a time in milliseconds. For example, communications link 64 between nodes 54 and 56 has a latency of 45 milliseconds.

Distance between the source and destination 50 and 52 may be determined in various ways. In the exemplary configuration of FIGURE 2, only hop count and latency between the source and destination 50 and 52 are considered, however, other measures

15

20

25

30

of network distance are also usable. The distance between the source and destination 50 and 52 may be determined by counting the number of nodes between the source node 50 and the destination node 52 ("hop count"). For example, the distance from source node 50 to destination 52 is three hops along the path defined by nodes 54 and 56 and is four hops along the path defined by nodes 58, 60 and 62. Each hop represents one communication link 64 that a packet traverses. Thus, from source node 50 to node 54 is one hop, from node 54 to 56 is another hop, and from node 56 to destination node 52 is another hop.

The latency of communications links 64 may also be considered in determining network distance. For example, a packet traveling from source node 50 to node 54 will take five milliseconds to travel across the communications link 64 between source node 50 and node 54. Similarly, a data packet traveling from source node 50 to node 58 will experience a ten millisecond delay as the packet crosses communications link 64 between source node 50 and node 58. The total experienced by a data packet traveling from source node 50 to destination node 52 is the sum of the latencies of each communication link 64 traversed on the path from source node 50 to destination node 52. Thus, the latency from source node 50 to destination node 52 along the path defined by nodes 54 and 56 is sixty milliseconds (5 milliseconds + 45 milliseconds + 10 milliseconds). The total latency between source node 50 and destination node 52 along the path defined by nodes 58, 60 thirty milliseconds (10 milliseconds milliseconds + 5 milliseconds + 10 milliseconds). the number of hops between source node 50 and destination node 52 through nodes 54 and 56 includes fewer hops, the latency is much higher than along the path of nodes 58, 60 and 62.

10

15

20

25

30

considering both the number of hops and the latency, the distance between the source node 50 and destination 52 may be determined and the faster and shorter route can be chosen. Also, the latency of any particular communications link 64 may not be a fixed value. For example, the link 64 between nodes 54 and 56 is shown as 45 milliseconds which may result when a large amount of data is being communicated between nodes 54 As the amount of network traffic between 54 and 56 decreases, the latency may decrease as well. Thus, while in the exemplary network of FIGURE 2, the path across nodes 58, 60 and 62 has a lower latency than the path along nodes 54 and 56, at some other time the path along nodes 54 and 56 may be more optimal than the path along nodes 58, 60 and 62. determination of network distance discussed above is also applicable to determining which of a plurality of destination nodes has the shortest path from a single source node.

FIGURE 3 is block diagram illustrating details of web caching system 10. Data center manager 16 comprises a crawler application 29. Crawler application 29 comprises a software application executed by data center manager 16 for assisting administrator associated with origin server determining which content available from origin server should be cached at data centers 14, status information (described later in association with flow control server 34 and in detail in association with FIGURE 4) associated with particular content items, priority information (described in later in association with flow control server 34 and in detail in association with FIGURE 4) associated with requests, such as requests 22 and other suitable configuration information associated with controlling the caching of content from origin server 18. Data center 14 comprises a web server 30, a cache server 32, a flow control server 34 and communication links

20

25

30

Web server 30 is coupled to communications 36A and 36B. network 13 and is operable to receive request 22 and generate Web server 30 is further coupled to cache responses thereto. server 32 over communication link 36A. Cache server 32 is coupled to flow control server 34 over communication link 36B and to origin server 18 over network 13. Cache server 32 is operable to store content requested from web server 30 and provide requested content to web server 30. Flow control cache server 34 is operable to control server determining when cache server 32 may request content from origin server 18.

Web server 30 comprises any suitable server application operable to retrieve data in response to requests 22. disclosed embodiment, web server 30 comprises an HTTP server ("web server"), such as the Internet Information Server® by Microsoft Corp. of Redmond, Washington and the Apache web server by the Apache Software Foundation of Forest Hill, Web server 30 receives request 22 and examines request 22 to determine what content is requested by request Web server 30 then requests the desired content from 22. Alternatively, web server cache server 32. 30 mav determine whether the requesting user is allowed access to the requested content, decrypt Secure Socket Layer (SSL) encrypted content requests and then pass the request over to cache server 32 for handling. After receiving the requested content from cache server 32, web server 30 provides the requested content to browser 12.

One example of a cache server that could be used as cache server 32 is shown in FIGURE 5. Cache server 32 comprises a software program executing on a data processing system for storing and retrieving content in response to information requests from web browser 12. For example, cache server 32

10

20

25

30

may comprise the Squid caching application. Specifically, cache server 32 operates to store content, such as web pages, previously requested by browser 12.

In operation, cache server 32 provides transparent proxy, content caching, content synchronization, flow control functionality. Transparent response functionality comprises passing content and requests through cache server 32 and not altering the content or the request as seen by browser 12, origin server 18 or web server 30. Both browser 12 and origin servers 18 are typically unaware of the Content caching comprises storing, at cache proxy server. server 32, cacheable content that is served to browsers 12 by the proxy server functionality of cache server 32. The cached content may later be served to additional browsers 12 without going back to origin server 18. Cacheable content may be indicated by a set of headers associated with the content from origin server 18 and by the configuration of cache server 32. Cacheable content also comprises HTTP POST requests. element of the configuration of cache server 32 may specify that caching instructions in the headers of the content may be ignored. Content syncronization comprises preloading and expiring content stored at cache server 32. Flow control allows for each incoming content request to be subjected to a scoring mechanism that indicates the priority of the content request.

In the disclosed embodiment, a substantial portion of the content on cache server 32 will have been originally retrieved from origin server 18. Substantially little of the information available on cache server 32 is independently generated by cache server 32. Alternatively, cache server 32 may generate all or any portion of the content available on cache server 32. Cache server 32 and web server 30 may

15

20

25

30

optionally have their functionality combined into a single element such that cache server 32 provides suitable functionality to allow cache server 32 and flow control server 34 to handle requests 22 as described previously without the use of a discrete web server 30.

In operation, crawler 29 examines all or a portion of the web pages available at origin server 18. Crawler 29 generally communicates directly with web server 18 using the HTTP and HTTP Secure (HTTPS) protocols. Crawler 29 then hierarchically organizes the web pages for an administrator associated with origin server 18 (not shown) so that the administrator may determine which web pages should be cached at data centers 14. Crawler 29 also allows the administrator to configure status information and alternate content associated with particular content items, priority information associated with requests 22 and other suitable configuration information associated with controlling the caching of content from origin server 18. The configuration information provided by the administrator using crawler 29 is used to configure and control data centers Crawler 29 may alternatively determine automatically which web pages available at origin server 18 should be cached at data centers 14. When crawler 29 requires access to SSL secured web pages at origin server 18, crawler 29 communicates with origin server 18 through a crawler web server (not shown) similar to web server 32. The crawler web server is used to provide an SSL secured link between origin server crawler 29. The crawler web server appropriately encrypts and communications with origin server communicating using unencrypted communications with crawler 29.

Cache server 32 receives a request for information, such as request 22, from web server 30. Cache server 32 then

5

10

15

20

25

30

examines request 22 and determines whether the requested content is locally available and current on cache server 32. If the requested content is locally available and current on cache server 32, cache server 32 communicates the requested content to web server 30 over link 36A for communication back to browser 12. If the requested content is not available on cache server 32, cache server 32 communicates request 22 to origin server 18 under the control of flow control server 34 as described below. After requesting content, cache server 32 receives the requested content from origin server 18. server 32 then determines whether the retrieved content is cacheable. If the content is cacheable, then cache server 32 stores a copy of the content and then communicates the content to web server 30 for communication to browser 12. content is not cacheable, then cache server 32 does not store a copy of the information and passes the information to web server 30 for communication to browser 12. Cache server 32 determines whether content is cacheable based on configurable cache criteria (described in more detail in association with FIGURE 5). Cache server 32 is further operable to preload one or more content items. For example, cache server 32 may be configured by an administrator associated with origin server 18 to preload content items that the administrator knows will be accessed in order to further decrease the load at origin server 18.

Cache sever 32 determines whether content is locally available and current based on at least two criteria. The first criteria is whether the requested content is present at cache server 32. If the requested content is present at cache server 32, the second criteria is whether the requested content is current or expired. Each content item stored at cache server 32 may have a respective expiration time

10

15

20

25

30

associated therewith. Since some content may never expire, or may not have an expiration time known ahead of time, particular content item may or may not currently have a time associated therewith. respective expiration expiration time describes when the content item expires and is no longer valid. The expiration time is updateable and may be initially set as a function of the content item such as the expiration time used by the HTTP protocol. In the disclosed embodiment, the expiration time comprises a time and date indicating when the associated content item expires, such as with an offset indicating an amount of time that must elapse before the content item is expired. The expiration time may alternatively comprise any suitable representation representing when a content item expires. The expiration time may be accelerated, decelerated or otherwise changed by an expiration command 24.

Expiration command 24 is generated by data center manager 16 and indicates a change in the expiration time associated with one or more items of content on cache server 32. In the disclosed embodiment, expiration command 24 comprises an Internet Cache Synchronization Protocol (ICSP) terse command (described in detail in association with FIGURE 4).

Expiration command 24 is generated by data center manager 16 in response to data change message 28 from data source 20. Data change message 28 is generated by trigger 21 associated with data source 20. Trigger 21 detects a change in one or more content items available from data source 20. Trigger 21 then generates data change message 28 indicating which content items have changed and communicates data change message 28 to data center manager 16. Data center manager 16 then generates one or more expiration commands 24 to expire the cached copies of the changed content items at one or more data centers 14.

5

10

15

20

25

30

For example, if an airline flight schedule has changed at data source 20, then the airline would not want customers receiving invalid flight schedules from data centers 14. Therefore, trigger 21 detects the change and communicates the change to data center manager 16. Data center manager 16 then informs data centers 14 of the change so that when a request for the flight schedule arrives at one or more data centers 14, data centers 14 will know to request a new copy of the flight schedule from origin server 18 associated with data source 20. In the disclosed embodiment, data centers 14 and specifically cache server 32, do not request a new copy of expired content response to a request 22 for that content. in Alternatively, cache server 32 could actively request a new changed content in response to the expiration command 24. Note that since cache server 32 does not request a new copy of changed content in response to expiration command 24, it is possible and expected that cache server 32 may receive multiple expiration commands 24 expiring the same content. When multiple expiration commands 24 are received by cache server 32 which each expire the same or overlapping content, cache server 32 may repeatedly mark the expired content as expired, but will retrieve new content only in response to an appropriate request 22. By not updating the expired content after each expiration command 24, cache server 32 decreases the network and processing load on origin server 18 by not requesting content that browsers 12 may not request for a long period of time or before the next expiration command 24 expiring that content. This provides a significant decrease in the processing and network load experienced by origin server 18 by avoiding retrieval of unused and yet to be requested content by cache server 32.

10

20

25

30

One example of a flow control server that could be used as flow control server 34 is described in association with FIGURE 4. Flow control server 34 is operable to control and regulate the passing of information requests, such as requests 22, from cache server 32 to origin server 18. Flow control server 34 operates to monitor the processing and network load on origin server 18. Cache server 32 requests permission from flow control server 34 to request locally unavailable content from origin server 18. Flow control server 34 determines whether cache server 32 may request content from origin server 18 based on the processing and network load on origin server 18.

In addition to controlling whether cache server 32 can request locally unavailable content from origin server 18, flow control server 34 is operable to determine the order in which requests for locally unavailable content communicated from cache server 32 to origin server 18. Flow for server 34 may order the requests unavailable content as a function of various load criteria (described in detail in association with FIGURE 6) configured by an administrator associated with origin server 18, such as a current state associated with each request. For example, cache server 32 requests permission to forward two requests to origin server 18, the first request is a search request for product information by a first user and the second request is from a second user to buy a product from request site. Flow control server 34 electronic commerce prioritize and order the first and second requests so that the second request is handled first, because the administrator has indicated that buy requests should get immediate handling so that the user does not get impatient and abort the order while search requests which are less important are occupying the

10

15

20

25

30

Additionally, flow control server 34 could order the first and second requests based on information associated with the first and second users, such as the buying history or amount of money previously spent by the first and second users. Flow control server 34 evaluates the processing and network load on origin server 18 according to user-specified criteria to determine if cache server 32 may request content from origin server 18. For example, the user may specify that 90% its maximum should not exceed of origin server 18 processing capability. For another example, the maximum number of simultaneous connections may be limited to some number, such as 5,000. For yet another example, flow control server 34 may periodically interrogate origin server 18 to determine the current load and the criteria may specify the maximum allowable load on origin server 18 as a function of the response of origin server 18 to the interrogation, such as how long origin server 18 take to return a requested web page.

When flow control server 34 does not allow cache server 32 to request content from origin server 18, cache server 32 may be instructed to return status information to web server Status information comprises information alerting browser 12 that processing of request 22 is in process, but will be For example, status information may describe the length of time before request 22 will be processed. status information may also list the position of request 22 in a queue of requests to be processed. The status information may also present an advertisement to a user of browser 12. For example, the advertisement may be generated based on information previously gathered about the user associated with browser 12. Generally, the status information configurably provide any suitable information to the user associated with browser 12 as determined by the administrator

15

20

25

30

associated with origin server 18 and configured into the load criteria for origin server 18. In the disclosed embodiment, the status information comprises an HTML web page generated based on load criteria determined by the administrator associated with origin server 18.

Data links 36A and 36B comprise the data communication portion of data center 14 and support communication between web server 30, cache server 32 and control server 34. links 36A-B may comprise any suitable wireless and wireline Data links 36A-B may also comprise a computer networks. computer bus and any other suitable combination of hardware and software operable to support communication between web server 30, cache server 32 and flow control server 34. two or more of web server 30, cache server 32, and flow control 34 are executing on a single physical computer, then data links 36A-B comprise data communication systems communicating between programs and within programs executing on a single physical device. For example, if web server 30 and cache server 32 are both being executed by the computer, then data link 36A may comprise physical peripheral component interface (PCI) bus for transferring data between web server 30 and cache server 32. For another example, when web server 30 and cache server 32 are executing on separate physical devices, then data link 36A may comprise an Ethernet network. Data links 36A-B may represent two distinct data communication systems, portions of a single data communications system, or any suitable combination thereof. For example, data link 36A may comprise an Ethernet network while data link 36B represents a computer bus.

FIGURE 4 is a block diagram illustrating details of a flow control server 134. FIGURE 4 illustrates a general flow control server for increased clarity and the application of

15

20

25

30

the general flow control server to flow control server 34 will be shown. Flow control server 134 operates to regulate and control the flow of data requests from a network device which desires data and a network device having the data. Flow control server 134 comprises one or more queues 100, one or more sets of priority criteria 102, one or more load monitors 104 and one or more sets of load criteria 106. Flow control server 134 is coupled to a flow controlled device 110 over a communications link 112 and to a protected resource 120 over communications link 122. Flow controlled device 110 and protected resource 120 communicate over communications link 130.

Queue 100 comprises a computer readable memory of any suitable type, such as random access memory, magnetic memory and optical memory. Queue 100 stores a plurality of data requests 136.

Priority criteria 102 comprises information provided by administrator (not shown) associated with protected 134 for determining the relative resource 120 to server importance of requests for data from device 110 to resource Priority criteria 102 may specify that specific types 120. and groups of requests be given specific priority levels while other requests be given a default priority. For example, a product buy request at an e-commerce site or an add to shopping cart request may be given a higher priority, while a request for a product catalog may be given a lower priority or a default priority. For another example, a higher priority may be given to requests originating from a particular IP address because empirical data suggests that that IP address has a high probability of buying. For yet another example, priority criteria 102 may track purchasing patterns at an ecommerce site and determine that certain products have a

10

15

20

25

30

higher probability of actually being purchased after being added to a shopping cart. Also, priority criteria 102 may be updated dynamically. For example, if a particular product suddenly becomes a popular item, priority criteria 102 can automatically adjust to the increased popularity of the item and assign a higher priority to requests related to that item.

Load monitor 104 comprises an application program for processing and determining the current monitoring Load criteria 106 comprises experienced by resource 120. information provided by the administrator associated with resource 120 to server 134 for determining the maximum load server 134 should allow resource 120 to experience. For example, load criteria 106 may specify that resource than 10,000 should experience no more simultaneous For another example, load criteria 106 connections. specify that resource 120 not be loaded beyond 90% of the resource's processing capability. Also, load criteria 106 may specify the maximum allowable load as a function of response of server 120 to interrogation by server 134.

Communications links 112, 122 and 130 may comprise any suitable data communication system operable to support communication between device 110, server 134 and resource 120. In the disclosed embodiment, links 122 and 130 each comprise a portion of the Internet and link 112 comprises an Ethernet link.

In operation, flow controlled device 110 desires to retrieve data from protected resource 120. Before retrieving data from protected resource 120, flow controlled device 110 requests permission to retrieve data from flow control server 134 by sending a flow request 132 over link 112. Flow request 132 includes data request 136 that device 110 wishes to send

15

20

25

30

to resource 120. Specifically, device 110 will generate flow request 132 with data request 134 therein.

Flow control server 134 receives flow request 132 and determines whether to grant or deny permission to device 110 to request data from resource 120. Flow control server 134 then determines the current processing load at resource 120 and determines if the current processing load at resource 120 exceeds load criteria 106 for resource 120.

When the current processing load at resource 120 is below load criteria 106, then server 134 grants permission to device 110 and device 110 retrieves the desired data from resource 120. When the current processing load at resource 120 exceeds load criteria 106, server 134 may deny permission to device 110 to retrieve the desired data from resource 120.

Load monitor 104 communicates with resource 120 over link 122 to maintain current load information about resource 120. Any suitable load metric and combinations of load metrics for representing the current resource and processing load on For example, the number resource 120 may be used. simultaneous connections currently being supported by resource 120 may be monitored. For another example, load monitor 104 may interrogate resource 120 to determine the current load, such as by retrieving one or more Uniform Resource Locators from resource 120 and observing the response (URLs) resource 120. For yet another example, resource 120 may further comprise a monitoring application 140 for collecting suitable load information about resource 120 and communicating the load information to load monitor 104 over link 122. example, application 140 may monitor the CPU load on resource 120.

Server 134 then associates a priority value with data request 136 based on priority criteria 102 associated with

10

15

20

25

30

resource 120. In the disclosed embodiment, the priority value comprises an integer value between 1 and 10, but may comprise any suitable value having order. Server 134 then stores the prioritized data request 136 in queue 100 based on the priority value. Server 134 then removes the highest priority request currently in queue 100 and returns this request to device 110 with permission to send this request to resource 120 and retrieve the associated data when resources at resource 120 are available to process the request.

When prioritized request 136 is inserted into queue 100, prioritized request 136 is inserted into queue 100 based on the associated priority value. Specifically, queue 100 is sorted first on the priority value associated with each request in queue 100. Prioritized requests With equal priority values are ordered in a first-in, first-out order. Alternatively, other suitable arrangements for ordering prioritized requests in queue 100 may be used.

In addition, when server 134 denies permission to device 110 to retrieve information from resource 120, server 134 may specify that device 110 return a status page 138 or other alternate content to an associated user (not shown) generated request 136 based on priority criteria 102. page 138 comprises any suitable alternate content returned as a function of priority criteria 102 and load criteria 104. the disclosed embodiment, status page 138 comprises an HTML Specifically, server 134 provides a Uniform Resource Locator (URL) to device 110 which specifies the web page device 110 should retrieve as status page 138 in place of the web page requested by data request 136. For example, status page 138 may comprise a web page dynamically generated by a web server other than resource 120 based on the URL provided by server 134. Typically, the specified status page 138 will

15

20

25

30

include an automatic resubmission time, such as ten seconds, for re-issuing request 136. Alternatively, any suitable type of alternate content may be returned to the associated user instead of the content requested by request 136. One advantage of returning status page 138, instead of simply waiting for a timeout or returning "server too busy", to the user is that the user can receive a more useful and userfriendly response than "server too busy." Also, "server too busy" response is returned, in traditional systems, the original request is lost. Device 110 would then need to resubmit the request to have the request processed. If the request was to buy an item, and device 110 does not resubmit the request, the sale would be lost. In contrast, server 134 stores the request for later processing and the sale would not be lost. Also, by allowing the HTTP connection to close after receiving the status page, resources at both the client requesting the content and any servers which the client has contacted are released for other uses.

Priority criteria 102 may also specify alternate content, such as status page 138, or replace the requested content with replacement alternate content 139 based on the communication bandwidth available to the user who Specifically, priority criteria 102 generated request 136. may specify temporary alternate content, such as status page 138, or replacement alternate content 139 for a particular request 136 for each of a high-bandwidth connection, a mediumbandwidth connection and a low-bandwidth connection. The definition of high, medium and low are configurable by an administrator associated with resource 120. For example, the administrator of a streaming media web site may define "high" bandwidth differently from the administrator of a text-based news site. For example, in the disclosed embodiment, request

10

15

20

25

30

136 may request http://www.domain.com/stuff.jpg and priority return stuff1.jpg for a criteria 102 may low-bandwidth connection, stuff2.jpg for a medium-bandwidth connection and stuff3.jpg for a high-bandwidth connection as replacement For another example, in operation, alternate content 139. request 136 is queued in queue 100 by flow control server 134 and the appropriate status page 138 is returned. Continuing the example, request 136 is then released from gueue 100 and priority criteria 102 is used to determine that request 136 should have high-bandwidth alternate content 139 returned instead of the content requested by request 136. another way, status pages 138 and alternate content 139 are mutually exclusive since request 136 could have particular status page 138 returned and then have alternate returned instead of content 139 the requested Further, either, both or neither of the particular status page 138 and alternate content 139 may be determined based on the bandwidth available to the user who originated request 136. Alternatively, a larger or smaller set of connection types may defined by priority criteria 102. example, For administrator associated with resource 120 could specify five different types of connections based on differing amounts of available bandwidth.

138 may also be delayed before page retrieved. Ιf the originally requested content becomes available before the delivery of status page 138, then the originally requested content will be returned instead of status page 138. For example, an administrator associated with resource 120 may know that a 1 second delay is common for resource 120 and specify that status page 138 not be delivered for 1.5 seconds to account for the expected 1 second delay. The administrator can use the delay functionality to control

10

20

25

30

the return of status pages 138 only when resource 120 is experiencing delays longer than an expected delay.

An example illustrating status page 138 and flow control server 134 is provided for increased clarity. generates data request 136 in response to a desire for content from a user associated with device 110. Device 110 then generates flow request 132, includes data request 136 therein, flow request 132 to server 134. determines the current load on resource 120 and, purposes of this example, determines that resource 120 is currently too heavily loaded to currently handle request 136. Thus, server 134 prioritizes request 136 and stores request 136 in queue 100. Server 134 also consults priority criteria for resource 120 and determines that status page should be sent to the user. Priority criteria resource 120 specifies that a URL for a web page that will 100 of request the position in queue 136 and be automatically re-submitted in ten seconds should be returned, such as:http://www.domain.com/status page.asp?queue position= 10resubmit=10. Server 134 then responds to flow request 132 and informs device 110 to retrieve the URL. Device 110 then retrieves status page 138. Note that flow control server 134 may have knowledge of the expected time until resource 120 handles the request and may set the automatic resubmission time to be slightly longer than the time resource 120 will take to process request 136. Specifically, server 134 knows that resource 120 will take 9 seconds to process request 136 server 134 sets the automatic resubmission time to 10 seconds so that when request 136 is re-submitted to resource 120, the response is already available and the user sees a very fast response time.

15

20

25

30

In an alternative embodiment, the functionality of flow control server 134 is used to provide content filtering. this embodiment, protected resource 120 comprises the Internet and flow controlled device 110 comprises a computer attempting to access the Internet. Load criteria 106 specifies that all or substantially all data requests 136 should be stored in queue 100 before being passed to the Internet. criteria 102 specifies that status pages 138 should be sent based on the type of data requested by data request 136. Specifically, priority criteria 102 specifies that status page should be returned when data request 136 requests restricted or illegal data. For example, in a country where certain types of data, such as images involving nudity, are illegal, priority criteria 102 may specify that a "Materials Illegal" status page 138 be returned when illegal data is requested and that the queued request 136 for illegal data be discarded without being passed on to the Internet. another example, priority criteria 102 may specify a legal version of the requested illegal data that is to be returned instead of the illegal data. Priority criteria 102 may evaluate whether the requested data is illegal data based on the geographic origin of request 136, external information associated with a user who generated request 136, the data requested by request 136 and any other suitable criteria.

In the disclosed embodiment of FIGURES 1 and 3, device 110 comprises cache server 32, server 134 comprises server 34, resource 120 comprises origin server 18 and data request 136 comprises request 22. Also in the disclosed embodiment, the Flow Control Protocol (FCP) (described below) is used to support the flow control functionality described above, such as flow request 132.

15

20

25

30

The Flow Control Protocol (FCP) is used to exchange messages between the flow controlled device and the flow control server. The FCP may also be used for communication among any number of flow control servers 134. The FCP is described here in terms of the World Wide Web (WWW), but could be used in any suitable environment for controlling data flow between a flow controlled device and a protected resource.

FCP Overview

When a flow controlled device receives a request, it sends an **initial request message** to the flow control server to gain permission to send the request to the origin server. The flow control server responds with an **initial response message**. This message indicates go (send) or no go (do not send). If the response is go, the flow controlled device is allowed to send the request to the protected resource.

If the message indicates no go, the flow controlled device must wait until the flow control server sends it a request to send message. This messages gives the flow controlled device permission to send the request to the protected resource.

The flow controlled device responds to the subsequent request by returning a **response status message** to the flow control server indicating how many requests were received, how many were processed, or if an error occurred.

In the event that a flow controlled device quits and another flow controlled device receives the request ID intended for the original device, the new device must send an ownership transfer message to the flow control server so it can "own" the request. The flow control server responds to the flow controlled device with an ownership assignment message.

10

If the flow control server has no record of the request, it must broadcast an ownership query message to the remaining flow control servers to see if the request resides on any of them. The flow control servers return an ownership query response message indicating the request.

Initial Request Message

When a flow controlled device receives a request from a browser, it sends an initial request message to the flow control server to gain permission to send the request to the origin server. The initial request message uses the following syntax:

TABLE 1 defines the values in the message syntax.

Field	Meaning
xxxx	The length of the entire message.
	The maximum length of the message
	is 4127 bytes, which is composed of
	a maximum message length of 4092,
	plus the length and ID fields.
	Valid integers for the length are
	0032 - 4127. If the length is fewer
	than four digits, use zeros for
	padding.
xxxxxxxxxxxxxxxxx	The Globally Unique Identifier
	(GUID). This identifier is uniquely
	associated with the request. Each x
	represents a character. The GUID
	length is 22 characters.
Request	The entire http request. The
•	request cannot be more than 4096

15

TABLE 1

An example of an initial request is shown below. The request portion is only intended as a representation and is not a full request.

5 [L0077] [127.000.000.001-

Ofb450]GET/http://xfiles.domain.com/test/d.html

Note: There are no spaces between the brackets.

Initial Response Message

The flow control server bases its response to the device upon various criteria, such as the load on the origin server. If the number of requests to the protected resource surpasses its designated maximum load, the flow control server will not allow the flow controlled device to send the request. The flow control server sends an initial response message to the flow controlled device using the following syntax (note that "\t" indicates one tab stop between values):

GO NOGO \tPause \trefresh rate \tstatusURL \n

TABLE 2 defines the values in the message syntax.

Field	Meaning
GO NOGO	The response is either GO or NOGO.
	GO indicates the flow controlled
	device has permission to send the
	request to the origin server. NOGO
	indicates that the flow controlled
	device cannot send the request to
	the origin server until it receives
	a subsequent response message with
	a value of GO.
Lea Louis La	

Pause	A whole number indicating the length, in seconds, which to pause before sending a status page to the requesting browser. If the content is available before the time expires, a status page is not sent. Note: The pause value can be zero whether or not there is a status
Refresh	page URL. A whole number indicating the length, in seconds, which to wait before resubmitting the GUID to the flow controlled device. Note: The refresh value cannot be zero if there is a status page URL.
StatusURL	The URL of the status page to send to the requesting browser. If there is no status page URL, the value can be null. Note: If the value is null, the pause and refresh values must both be zero.
\n	Indicates line feed.

TABLE 2

Example initial responses are shown below.

GO\t3\t7\thttp://www.company.com/statuspage.htm\n

This message indicates that the flow controlled device can send the message to the origin server. The pause time of 3 seconds indicates that if the request takes more than 3

seconds to return from the origin server, the flow controlled device is to send the indicated status page to the browser. The status page will resubmit the GUID to the flow controlled device in 7 seconds to check if content is available. If yes, the content is returned. If no, another status page is returned that will resubmit in 7 seconds.

In the example below, the flow controlled device is instructed not to send the request. There are no other values.

NOGO\t0\t0\t\n

10 Request to Send Message

If the initial response message is NOGO, the flow control server sends a request to send message when it is ready to give the flow controlled device permission to send the request to the origin server. The flow control server sends the message using the following syntax:

 $GO?GUID1 \setminus nGUID2 \setminus nGUID3 \setminus n \setminus n$

TABLE 3 defines the values in the message syntax.

Field	Meaning
GO	GO indicates the flow controlled
	device has permission to send the
	request to the origin server.
1-n GUIDs	A subsequent request message can
	contain any number of GUIDs.
\n	Indicates line feed. Each GUID must
	be separated by \n.
\n\n	Indicates the end of the message.

TABLE 3

The example below shows a subsequent request message.

10

20

GO?127.000.000.001-0fb450\n127.000.000.001-0be390\n127.000.000.001-0da040\n\n

Response Status Message

When a flow controlled device receives a subsequent response message, it sends a response status message to the flow control server indicating how many requests were received and how many were processed. These numbers should be the same if no errors occurred. If an error occurs, the status message will either indicate an error or the two numbers will not be the same.

Ownership Transfer Message

When a flow controlled device sends a status page URL to a browser, the refresh value in the response message indicates the browser will resubmit the GUID to the device at defined intervals. When the GUID is resubmitted, it assumes that the request lives in the flow controlled device that originally serviced the request.

In cases where the flow controlled device has stopped, the resubmitted GUID will go to another flow controlled device. However, the initial request does not reside on this device, so the flow controlled device is unable to associate the GUID with a request. The new device must gain ownership of the request by sending an ownership transfer message to the flow control server.

25 Ownership Assignment Message

In response to the ownership transfer message, the flow control server sends the flow controlled device an ownership assignment message. This message indicates the request that is associated with the GUID.

15

20

25

Ownership Query Message

In cases where both the flow controlled device and the flow control server have stopped, the ownership transfer message will reach a flow control server that has no record of the request. The flow control server must broadcast an ownership query message to the remaining flow control servers to determine the request.

Ownership Query Response Message

Flow control servers that receive an ownership query message respond to the requesting server with an ownership query response message. This message notifies the querying flow control server of the request associated with a particular GUID.

FIGURE 5 is a block diagram illustrating details of a cache server system 200. FIGURE 5 illustrates a general cache server for increased clarity and the application of the general cache server to cache server system 32 will be shown. FIGURE 5 is discussed in terms of the Internet Protocol (IP), however, any suitable network protocol, such as ATM, frame relay and others, may be used.

Cache server system 200 comprises a cache server portion 202 and a dispatch server portion 204. Cache server system 200 is coupled to a web client 206 via a communications link 208 and to an origin server 210 via a communications link 212. Web client 206 is coupled to a DNS server 214 via a communications link 216. Origin server 210 is further coupled to a data source 218.

Web client 206 comprises any suitable HTTP client operable to communicate with system 200 over link 208. In the disclosed embodiment, web client 206 comprises a web browser such as Internet Explorer. Origin server 210 comprises

10

15

20

25

30

software executing on a computer for receiving and responding to one or more data requests, such as requests 22 and requests Origin server 210 may comprise a single computer executing software, a plurality of computers each executing software or may comprise hardware with similar functionality. In the disclosed embodiment, origin server 210 comprises a single computer executing an HTTP server which is remote from system 200. Origin server 210 retrieves information from data source 218 in response to data requests. Similar to origin server 18, origin server 210 is operable to retrieve static content and to generate new, dynamic content. For example, origin server 210 may generate a new web page using a common gateway interface (CGI) script, generate a new web page from the result of a structured query language (SQL) request and perform other suitable content generation also be operable to Origin server 210 may functions. applications executable software, such as generate in response to requests for data. For example, origin server 210 may generate a Java applet in response to an appropriate data request.

DNS server 214 comprises any suitable DNS server operable to communicate with client 206 over link 216 and provide DNS resolution services to client 206. Specifically, DNS server 214 translates Internet domain names and machine names into the IP address associated that machine and domain.

Data source 218 comprises magnetic storage devices, optical storage devices, persistent storage devices, transient storage devices, and any other suitable storage device or technology for storing data. For example, data source 218 may be a Relational Database Management System (RDBMS) or an Oracle database. Data source 218 may comprise a portion of origin server 210 or may be physically separate therefrom.

15

20

25

30

Data source 218 includes a trigger portion 220. Trigger portion 220 comprises an application program, applet, software within a database, or other suitable executable software associated with data source 218 and operable to detect a change in the data stored at data source 218. Trigger portion 220 generates data change message 28.

Data change message 28 comprises any suitable message operable to indicate a change in the data or any portion of the data stored at data source 218. In the disclosed embodiment, data change message 28 comprises an Internet Cache Synchronization Protocol (ICSP) verbose message (described below).

Cache server 202 comprises cache criteria 222 and a software program executing on a data processing system for storing and retrieving content in response to information Specifically, cache server 202 requests from web client 206. operates to store content, such as web pages, previously In the disclosed embodiment, a requested by web client 206. substantial portion of the content on cache server 202 will been originally retrieved from origin server 210. Substantially little of the information available on cache server 202 is independently generated by cache server 202. Alternatively, cache server 202 may generate all portion of the content available on cache server 202.

Cache criteria 222 comprises criteria provided by an administrator associated origin server 210 for determining which content available from origin server 210 should be cached. Cache criteria 222 may comprise any suitable criteria used to allow cache server 202 to determine whether content should be cached. In the disclosed embodiment, cache criteria 222 comprises one or more URLs specifying web pages that should be cached and web pages that should not be

20

25

The specified individually, cached. URLs may be http://www.domain.com/dont cache me.html, or wildcards, such as http://www.domain.com/dont cache directory/ for multiple files and http://*.no cache servers. domain.com/*.html for multiple machines. Each origin server 210 may have distinct cache criteria 222. For example, cache criteria 222 may specify that certain web pages that could be cached should not be cached, such as pages containing a user's credit card number. For another example, cache criteria 222 may specify that certain web pages should not be cached because the nature of the web page makes caching useless, such as credit card transactions which are only valid for that single credit card transaction.

Dispatch server 204 is coupled to data source 218 and cache server 202. Dispatch server 204 operates to expire content at cache server 202. Dispatch server 204 expires content at cache server 202 by sending data expiration commands 24 to cache server 202.

Cache server 202 and dispatch server 204 may both be located on a single physical computer system or may be located on separate computer systems. Further, cache server 202 may comprise multiple computer systems each providing caching services. For example, cache server 202 may comprise a server farm with a router (not shown) dispatching requests to individual elements of cache server 202 for handling.

Data expiration command 24 comprises any suitable message for expiring data at cache server 202. In the disclosed embodiment, data expiration command 24 comprises an ICSP terse message (described below).

The ICSP terse command may expire any of a single web page, a plurality of web pages at a single web site, a plurality of web pages at a plurality of web sites, a

20

25

30

plurality of sites within a single domain and one or more specific objects on a web page, such as an image. example, the ICSP tease command may expire a single web page such as http://www.domain.com/web page.html. The ICSP terse command may expire a plurality of web pages at a single web site such as http://www.domain.com/web pages/* which would expire all web pages in the "web pages" directory at the site The ICSP may expire a plurality of pages at a www.domain.com. plurality of web sites such as http://*.domain.com/web pages/* which would expire all web pages in the "web pages" directory The ICSP terse command may of each site in "domain.com". expire a plurality of web sites such as http://*.domain.com which would expire all web pages on all sites in "domain.com". For another example, a single active server page (ASP) may result in many individual cached pages. A single ASP page may generate large numbers of individual cached pages because a single ASP page can dynamically create multiple different http://www.domain.com/product pages, such as description.asp?category= &product= may specify page that generates many specific product description pages on a specified category and product. based product description.asp?category=5&product=7, server 202, product description.asp?category=5&product=6 and product description.asp?category=3&product=7 specify three different. cached expiring pages. By product description.asp?category=*&product=7 ALL categories of product seven are expired, while not effecting product six related pages even though all of the pages were generated from a single ASP page.

Data links 208, 212 and 216 may comprise any suitable networking system or technology operable to support communication between DNS server 214, web client 206, cache

15

20

25

30

system 200 and origin server 210. In the disclosed embodiment, data links 208,212 and 216 each comprise a portion of the Internet.

In operation, origin server 210 contracts with cache system 200 for caching services. In order to provide caching services, an administrator associated with origin server 210 configures DNS server 206 or allows DNS server 206 to be configured to resolve one or more machine and domain names associated with origin server 210 to resolve to cache system 200 instead of origin server 210. Stated another way, after contracting for service, domain names and machine names associated with origin server 210 will translate into one or more IP addresses associated with cache system 200.

Web client 206 generates a data request for content from Web client 206 consults DNS server 214 origin server 210. 216 to translate the machine and domain name associated with origin server 210 into an IP address. origin server 210 has contracted for caching services from cache system 200, the IP address returned for origin server 210 is actually an IP address associated with cache system The IP address associated with cache system 200 may be 200. an IP address identifying cache server 202, a particular cache server 202 out of a farm of cache servers 202 or a router associated with a farm of cache servers 202 (not shown) for routing requests to a specific cache server 202 out of the farm of cache servers 202. Web client 200 then communicates the data request to cache system 200 over link 208 based on the IP address returned from DNS server 214.

Cache server 202 receives the data request from web client 206 and determines if the requested content is stored and current at cache server 202. If the requested content is stored and current at cache server 202 then cache server 202

15

20

25

30

will return the requested content to web client 206. requested content is either not stored or not server 202, cache server 202 ("expired") at cache retrieve the requested the data from origin server 210. retrieving the requested data from origin server 210, cache server 202 will determine whether the requested data is cacheable based on caching criteria 222 for origin server 18. If the requested data is cacheable, then cache server 202 stores a copy of the requested data and returns a copy of the requested data to web client 206. In the disclosed embodiment, cache server 202 is operable to ignore the "no cache" directive associated with the HTTP protocol.

Trigger portion 220 of data source 218 generates data change message 28 indicating a change in the content or portions of content available from origin server 210 and stored in data source 218. Trigger portion 220 may also indicate a change in the data based on the time and date. For example, trigger portion 220 may know that certain content changes at periodic intervals at data source 218, such as when data source 218 is a file system and trigger portion 220 is a process monitoring the file system for changes, and generate data change message 28 for that content independently of detecting a change in the content.

Dispatch server 204 generates data expiration command 24. For example, dispatch server 204 may generate data expiration command 24 in response to a change in the content at data source 218. Specifically, dispatch server 204 generates data expiration command 24 in response to data change message 28 from data source 218. Dispatch server 204 may also generate data expiration command 24 in response to the elapsing of a predetermined time period. For example, if a previously received data change message 28 specified that the expiration

10

20

of the data at cache server 202 should not occur for a set period of time, then dispatch server 204 will wait that set period of time before expiring data at cache server 202 by generating data expiration command 24.

The Internet Cache Synchronization Protocol (ICSP) is used to exchange messages to synchronize cached content with updated content. ICSP uses two levels of messages. ICSP Level 1 messages are sent with the HTTP protocol. ICSP Level 2 messages are sent via sockets on the same network level as, but independent of, the HTTP protocol. Both levels specify an ICSP request and an ICSP response. For both levels, an ICSP request typically specifies a list of URLs and the operations to perform on them, such as expiring them in the cache or removing them from a cache list. A request also includes a header specifying information about the protocol, domain, requesting agent IP and type, and time.

For both levels, the request message can be either terse or verbose. Cache servers, such as cache server 202, listen for terse messages, which indicate the action should occur immediately. Dispatch servers, such as dispatch server 204, listen for verbose messages, which indicate a particular time for the action to occur and specify the interval at which the action should reoccur.

Request Header Fields

Request Header Field	Meaning			
Version	Protocol	version,	expressed	as
	ICSP/x.x			
Domain	Domain t	co which	the mes	ssage
	applies. F	For example,	domain.co	m
Requesting-Agent-IP	The reques	sting agent	IP. This	can

20

	be omitted if you are already using HTTP.
Requesting-Agent-Type	The requesting agent type (ICSP Dispatcher or Client Gateway)
Request-Time	The time of the request in UTC format (milliseconds).

TABLE 4

Request Header Syntax for ICSP Level 1 Messages

The header is inserted into the HTTP header as shown in the following example.

Version: ICSP/1.0\r\n

Domain: domain.com \n

Note that " \n " represents a new-line character and " \r " a carriage return.

Request Header Syntax for ICSP Level 2 Messages

10 Unlike ICSP Level 1 request headers, a verbose request header is not inserted into an HTTP header. However, the Level 2 header must appear the same as an HTTP header, as shown in the following example:

Version: ICSP/1.0\n

15 Domain: domain.com \n\n

For terse requests, no header is required.

ICSP Verbose Request Message Body

In a verbose request, the message body contains messages that specify: an action to take, the URL on which to take the action, the time and interval at which the action on the URL will occur and the priority of the action on the URL.

10

15

20

25

30

Verbose request message syntax:

<Operation Code indicating action>\n
URL upon which to take action\n
UTC in milliseconds indicating when to take action\n
Interval in milliseconds indicating when to repeat
action\n

Integer indicating action priority\n <Operation Code indicating end message>

The only required elements of the verbose request are the operation codes and the URL. The remaining elements will use default values if not specified. Specifically, the default value for the UTC is 1, which represents that the action taken immediately, the interval zero which is represents no repetition and the priority is three out of a one to five scale. Because there are no labels for these listed elements, the order in which they are is very important. Therefore the interval and priority may not be also indicating the UTC, because the indicated without interval's value would be interpreted as the UTC and the priority's value would be interpreted as the interval since the values are interpreted based on their position. elements may be omitted in reverse order of the syntax. For example, all elements except the priority may be specified, since priority is the last element positionally, or elements except for the priority and interval, such these are the last two elements positionally.

TABLE 5 describes the actions and their associated operations codes that may be performed in a message. The actions are expire, add a new URL, remove a URL, rename a URL, and load a URL. For example, adding, loading, renaming and removing URLs may be used to modify caching criteria 202. To

receive an immediate response on the status for any of the actions, the code for a response action and the operation code number, such as R0 or R2 should be used. The operation codes in TABLE 2 would be inserted at the Operation Code indicating
action> and the Operation Code indicating
sections of the verbose request message as described above.

Operation Codes for Verbose Messages

Verbose	Meaning
Operation code	
<s0></s0>	Expire URL. This request flushes an
	object associated with a URL from the
	cache. The URL is cached again until the
	next time it is requested.
<s1></s1>	Add. This request adds a URL to the list
	of cached URLs. This allows a message to
	perform setup operations normally
	carried out in the administrative
	modules.
<s2></s2>	Remove. This request removes a URL from
	the list of cached URLs. This allows a
	message to perform setup operations
	normally carried out in the
	administrative modules.
<s3></s3>	Rename. This request renames a URL and
	can be used when a file, such as a gif
	or HTML page, is renamed.
<s4></s4>	Load. This request expires the URL, and
	then loads it into the cache before the

	first request comes. This is useful for
	items such as the graphics, which appear
	on several pages and rarely change. The
	load could be issued so that the first
	user does not have to wait for all of
	the images to be cached.
<ro></ro>	Respond to expiration request.
<r1></r1>	Respond to request to add URL.
<r2></r2>	Respond to request to remove URL.
<r3></r3>	Respond to request to rename URL.
<r4></r4>	Respond to request to load URL.

TABLE 5

Unlike send actions <S>, response actions <R> are synchronous. If in the message body there are no response actions, the entire message body is sent to dispatch server 204 at one time. However, if there are any response actions in the message body, that action must be sent to dispatch server 204 and on to cache server 202 and responded to before the remaining actions can be sent to dispatch server 204. Therefore, response actions can slow verbose messages.

10

For example, a verbose request messages may comprise:

<S0>\n

http://www.domain.com/index.html?param=value\n

9400000000000\n

15 100000\n

1 n

</S0>

15

URLs

The second element of the verbose request, following the operation code, is the URL upon which the specified action will take place. The URL is specified as the base URL and, optionally, one or more parameters. The URL can specify the value of one or more parameters and may include parameters, where applicable, for both POST and GET HTTP messages. The URL length is preferably no more than about 4 kilobytes, but may be longer in an alternate embodiment. ICSP level one messages are required to use URL style encoding because the ICSP level one message uses HTTP. Since the ICSP level two message uses sockets the URL encoding format is not required. Various examples are provided below for increased clarity. In each of the following examples, the action is to expire <50> (i.e. expire a URL).

To expire a specific page, include the page name in the URL: <50>

http://www.domain.com/foresite/jobs/programmer.dml

</S0>

In this example, the action applies only to the specific page. For example, if the page contained an image named splash.gif and it too should be expired, then its URL of the image must also be specified in the message, as shown in the following example:

25 <S0>

http://www.domain.com/images/splash.gif

</S0>

To expire specific parameters with specific values include the specific parameters to expire. In this example, the action

applies to this page only when the parameter position equals programmer and the parameter type equals fulltime.

<S0>

http://www.domain.com/foresite/jobs?position=programmer&type=f
ulltime

</S0>

5

10

To expire specific pages, regardless of the value of the page's parameters, include the specific parameters to expire and indicate their value with a wildcard, represented by an asterisk (*) for multiple characters. Other suitable wildcards may also be used, such as a wildcard for a single character.

<S0>

http://www.domain.com/foresite/jobs?position=*&type=*

</S0>

15 In this example, the action expires any page in the URL with values for position and type.

To expire a page, regardless of parameter name, value, or quantity all parameters may be replaced by an asterisk (*).

<S0>

20 http://www.domain.com/foresite/jobs?*

</S0>

Time

25

The third element of a request message body is time. The time that an action executes is specified in Universal Coordinate Time (UTC). Optionally, the time of execution may be specified as immediate, indicated by the value 1, and never, indicated by the value 9999999999.

In the following example, a specific time is indicated to expire the URL and, thereafter, every 100 seconds.

<S0>

http://www.domain.com/index.html?param=value

5 9400000000000

100000

<E>

In the next example, the request indicates to expire the URL now and, thereafter, every 100 seconds.

10 <S0>

http://www.domain.com/index.html?param=value

1

100000

<E>

15

20

25

30

Priority

The fourth element of the request message body is priority. For example, one of five priorities (1-5) may be assigned to a request. In general, all but the highest (1) priorities are relative and only apply to URLs within the specified domain. Other priority systems may be used in alternate embodiments of the present invention. Requests of higher priorities are guaranteed to execute before requests of lower priorities. The execution order of URLs within the same priority is first in, first out.

The only non-relative priority is the highest priority which, in this example, is 1. This priority means that the request may not be queued. It the request cannot be executed at the specified time, then it is not completed and generates an error.

In the following example, the request to remove a URL is given a priority level of 3.

<S2>

http://www.domain.com/whatsnew.html

8500000000000

0 .

5

3

<E>

10 ICSP Terse Request Message Body

In a terse request, the message body contains a message that specifies:

- An action to take
- The URL on which to take the action

In terse messages, the action is always expire. Because a terse request indicates the action should occur immediately, there is no need to specify time or a priority.

Terse request message syntax:

a?data type=data

20 where,

a = the action

? = delimiter

data type = the data type

data = the actual URL

25

Terse request message example:

x?url=http://www.domain.com/index.html?param=value

The following sections describe each element of the terse request message.

Operation Codes for Terse Messages

TABLE 6 describes the actions that may be performed in a terse message.

Terse	Description
Operation	
code	
x	Expire. This request flushes an URL from
	the cache. The URL is cached again the
	next time it is requested.
n	Start flow control. This starts the flow
<u>.</u>	control of a base URL by a flow control
	server such as server 134.
f	Stop flow control. This stops the flow
	control of a base URL by a flow control
	server such as server 134.

TABLE 6

ICSP Verbose Response Description

This section provides a description of the ICSP verbose response including:

- 10 ICSP Response Header
 - ICSP Response Message Body

Verbose Response Header

The ICSP verbose response header contains a message response and response code, as shown in the following example.

15 ICSP-Message:OK

ICSP-Code:100

15

ICSP Verbose Response Body

The ICSP verbose response body contains a message code and corresponding message text, as shown in the following example.

100: OK

5 ICSP Terse Response Description

The section provides a description of the ICSP terse response header. There is no message body associated with the response.

Terse Response Header

The ICSP terse response header contains the response code and corresponding message text, as shown in the following example.

100: OK

Ports

For ICSP Level 1 (HTTP), both verbose and terse messages are listened for on port 9092, but another suitable port may alternatively be used.

For ICSP Level 2 (sockets), verbose messages are listened for on port 1370, and terse messages are listened for on port 1827, but another suitable port may alternatively be used.

20

25

30

FIGURE 6 is a flowchart illustrating the data caching and dynamic flow control method of system 10. The method begins at step 300 where client 11 generates request 22 for content using browser 12. Next, at step 302, the data center 14 closest in network distance to client 11 is determined. In the disclosed embodiment, a DNS lookup is performed on request 22 which resolves to the internet protocol (IP) address of the data center 14 which is closest to client 11 in terms of network distance considering either or both of latency and hop count, or any other suitable metric for measuring network

15

20

25

30

Then, at step 304, data center 14 receives request distance. 22 to web server 30. communicates request 22 and Alternatively, request 22 is communicated to cache server 32 if web server 30 is not being used or has been merged into When cache server 32 and web server 30 are cache server 32. merged, cache server 32 provides all appropriate functionality described below as performed by web server 30. As web server 30 may comprise multiple physical servers each executing web server software, data center 14 may receive request 22 and then communicate request 22 to web server 30 having the lowest The processing load indicates, for example, processing load. the number of requests 22 which web server 30 is currently For example, if web server 30 comprises two physical computers running web server software, and the first computer is handling ten requests while the second computer is handling only five requests, then data center 14 would route the next incoming request to the second computer. Proceeding to step 306, the chosen web server 30 receives request 22 and begins processing the received request 22.

Next, at step 308, web server 30 determines whether browser 12 which initiated request 22 is allowed to access the requested content. Web server 30 may use any authentication system suitable for authenticating requests 22, such as HTTP requests. If browser 12 is not allowed to access the requested content then the NO branch of decisional step 308 is followed to step 310. At step 310, web server 30 returns an access denied response to browser 12 and the processing of request 22 ends. If the user is allowed to access the object then the YES branch of decisional step 308 is followed to step 312.

At decisional step 312, web server 30 determines whether request 22 is encrypted. Request 22 may be encrypted in order

15

20

25

30

to prevent the interception of the information contained within request 22. For example, if browser 12 and web server 30 are communicating using the Secure Sockets Layer (SSL) protocol then request 22 will be encrypted so that only browser 12 and web server 30 can read the contents of request Common uses of SSL comprise transferring credit card 12 and web 30 information between browser server performing electronic commerce. If request 22 is encrypted then the YES branch of decisional branch 112 is followed to step 314 where request 22 is decrypted. At step 314, request 22 may be decrypted using any of a variety of methods and the method proceeds to step 316. If the request is not encrypted then the NO branch of decisional step 312 is followed to decisional step 316. After the request is decrypted at step 314, the method proceeds to decisional step 316.

Then, at decisional step 316, web server 30 determines whether request 22 is a status page resubmission. described in more detail in step 348, flow control server 34 prevent cache server 32 from immediately requesting locally unavailable content from origin server 18. When cache server 32 is instructed to delay requesting unavailable content from origin server 18 by flow control server 34 then cache server 32 may return a status page to the associated with browser 12 which includes status information associated with the delayed processing of the may include an automatic The status page request. resubmission mechanism for updating of the status page. example, if the status page indicates a length of time that processing of request 22 will be delayed, then the status page may be automatically resubmitted after the stated period of time in order to get an update on the processing of the If request 22 is a status page resubmission, then

10

15

20

the YES branch of decisional step 316 is followed to step 348. When request 22 is not a status page resubmission then the NO branch of decisional step 316 is followed to decisional step 318.

318, cache server 32 determines decisional step whether request 22 is requesting a cacheable item of content. Cache server 32 is operable to examine the contents of request to determine whether the requested content cacheable. In the disclosed embodiment, the elements of the URL comprising request 22 are examined. Cache server 32 determines whether a content item is cacheable based on various configurable criteria. In the disclosed embodiment, the criteria determines whether the requested item of content is cacheable based on portions of the uniform resource locator (URL) associated with request 22. For example, when the URL associated with request 22 includes an authorization code for a particular electronic commerce transaction then the criteria can specify that the content item retrieved in response to request 22 should not be cached because electronic commerce authorization numbers are valid for only that one instance. In general, any portion or portions of the URL associated with request 22 may be used to determine whether the content item retrieved in response to request 22 is cacheable.

In addition, unneeded portions of a URL can be filtered
to increase the amount of content that is cacheable and
correspondingly decrease the load on origin server 18. For
example,

a URL comprising
http://www.domain.com/e_commerce/cgi-bin/query?id=1&flight=32
may represent a request for dynamically generated output from
a CGI script for a user with an identifier (id) of 1 for a
flight schedule for flight number 32. Cache server 32 can be
configured to cache and respond with the output of the URL

20

25

30

while ignoring the "id=1" portion of the URL. For example, the identifier value may not impact the information presented. Future requests for flight schedules for flight number 32 can be handled by cache server 32 regardless of the value of the "id" portion of the URL. In contrast, traditional caching techniques do not ignore the "id" portion of the URL and pass each request for a flight schedule for flight number 32 to origin server 18 which causes an increased processing load at origin server 18. Thus, cache server 32 treats both requests: http://www.domain.com/e_commerce/cgi-bin/query?id=1&flight=32 http://www.domain.com/e_commerce/cgi-bin/query?id=2&flight=32 as requests for the same content, specifically, "flight=32" because cache server 32 has been configured to ignore the "id" portion. In contrast, traditional web caching techniques

When cache server 32 determines that the requested content item is cacheable then the YES branch of decisional step 318 is followed to decisional step 320. When the cache server determines that the requested content item is not cacheable then the NO branch of decisional step 318 is followed to decisional step 324.

would pass both requests to origin server 18 for handling

because the different "id" values could not be ignored.

Next, at step 320, cache server 32 determines whether the requested item is available. If the requested item is available then the YES branch of decisional step 320 is followed to step 322 and the requested item is retrieved from cache server 32 and returned to browser 12. If the requested item is not available then the NO branch of decisional step 320 is followed to decisional step 324.

Proceeding to decisional step 324, cache server 32 desires to request locally unavailable content from server 18 and is requesting permission from flow control server 34 to

10

15

20

25

30

retrieve the locally unavailable content. Flow control server 34 determines whether origin server 18 is at capacity. determine whether origin server 18 is at capacity, control server 34 may determine the current processor and network load origin server 18. In the at embodiment, a load monitoring application (not provided from data center 14 to origin server 18 when origin server 18 contracts for service from data center monitoring the load at origin server 18 and communicating the load information to flow control server 34 over network 13. Flow control server 34 may also use other metrics and other methods for measuring the current load at origin server 18. If origin server 18 is not at capacity then the NO branch of If origin server decisional step 324 is followed to step 326. 18 is at capacity then the YES branch of decisional step 324 is followed to step 340.

Then, at decisional step 326, cache server received permission from flow control server 34 to request locally unavailable content from origin server 18. server 32 then determines whether request 22 was encrypted. If request 22 was encrypted then the YES branch of decisional step 326 is followed to step 328 where cache server 32 reencrypts request 22 so that request 22 cannot be intercepted between cache server 32 and origin server 18. If the request was not encrypted then the NO branch of decisional step 326 is followed to step 330. Then, at step 330, request 22, whether it is encrypted or non-encrypted, is communicated to origin server 18. Next, at step 332, the content item requested by request 22 is returned from origin server 18 to cache server Proceeding to decisional step 334, cache server 32 32. determines whether the content item retrieved from origin server 18 is cacheable. Cache server 32 may use criteria

15

20

25

30

similar to that used in step 318, or may use a different set of criteria. If cache server 32 determines that the retrieved item is cacheable then the YES branch of decisional step 334 is followed to step 336 where cache server 32 stores a copy of the retrieved content item. If the item is not cacheable then the NO branch of decisional step 334 is followed to step 338. In step 338, regardless of whether the retrieved item is cacheable, the item is communicated to browser 12.

decisional step 340, flow control determined that origin server 18 is at capacity and the At step 340 flow processing of request 22 may be delayed. control server 34 determines whether request 22 is requesting Flow prioritizable content item. control determines whether the requested content item is prioritizable based on various criteria. For example, at an electronic commerce web site, a request could be prioritized based on information previously gathered about the user associated with the request, such as how much the user has previously spent at The amount the user has the electronic commerce web site. previously spent could be used to give that user a high priority because of the user's repeat business, while a first time shopper could have a lower priority because the first shopper has a lower chance of purchasing an Continuing the electronic commerce web site example, the type of request from the user could be considered, such as whether the request is for more information about an item or a buy Higher priority could be attached to the request for an item. to buy an item that the request for information. If the requested item is a prioritizable item then the YES branch of decisional step 340 is followed to step 342 where a priority is associated with request 22 based upon the criteria and any of request 22, the data requested by

15

20

25

30

request 22 and external information associated with request 22 The external suitable combination. comprises information which is not part of request 22 itself, but has been associated with request 22 and the user which generated request 22. For example, the external information comprise historical shopping, statistical information collected about the user which generated request Request 22 is evaluated against the criteria using request 22, the data requested by request 22 and external information associated with request 22 in order to determine the priority to be associated with reguest 22. The method then continues to step 346. If the requested item is not prioritizable then the NO branch of decisional step 340 is followed to step 344 where a default priority is assigned to the request. The method then continues to step 346.

In the disclosed embodiment, the priority is a numeric value, but any suitable value which has order may be used. For example, an equation could be used to weigh multiple factors in order to come up with a single priority value. The numeric values range from 1 to 100, inclusive, where higher values indicate higher priority. The default priority may be set to any value as desired by an administrator associated with origin server 18 and in the disclosed embodiment may be from 1 to 100, inclusive. When a significant portion of the content available at origin server 18 is prioritizable, the default priority may be set to a low value, such as 25, because only unimportant activities are non-prioritizable. When a significant portion of the content available at origin server 18 is non-prioritizable, the default priority may be set to a middle value, such as 50, and the prioritizable items given high and low priorities based on their relative The middle value default priority may be used importance.

15

20

25

30

because most requests are roughly equal in importance to the administrator associated with origin server 18. Any suitable other method of calculating distribution, formula or priorities may be used with any suitable value for the default priority based on the desires of the administrator. servers 18 may have each distinct priority policies associated that flow control server 34 therewith can SO customized prioritizing service to each origin server 18.

Next, at step 346, the prioritized request is placed in a queue. The queue is sorted based on the priority associated with the prioritized request so that the highest priority requests are handled first.

Proceeding to decisional step 348, flow control server 34 determines whether the delay before the prioritized request is handled by origin server 18 exceeds a predetermined time The time limit is configurable based on origin server Specifically, since each data center 14 may be serving multiple distinct origin servers 18, each respective origin server 18 may have differing requirements for the status page and the time limit. Thus, flow control server 34 is operable to provide differing time limits and status pages based on the particular origin server request 22 was intended for. status page is also configurable as a function of request 22. If the delay is greater than the predetermined time limit then YES branch of decisional step 348 is followed to decisional step 350. At decisional step 350, flow control server 34 determines whether the requested item should have a status page sent.

The status page may comprise any suitable HTML data for use with browser 12. The location of the status page is indicated by flow control server 34 to provide information regarding the status of the processing of request 22 to the

10

20

25

30

user associated with browser 12. The status page may be located at, for example, cache server 32 or at other suitable locations. In situations where origin server 18 is incapable of handling the volume of requests for locally unavailable content, the status page may be generated. The status page may include an automatic resubmission element which causes browser 12 to communicate the status page back to web server 30 after a predetermined period of time. The status page may be resubmitted in order to update the status page with the status of request 22 after the predetermined time has elapsed originally requested if the return the content ororiginally requested content is available.

If the requested item should have a status page sent then the YES branch of decisional step 350 is followed to step 351 where a status page is communicated to browser 12 to inform the user associated with browser 12 of the status of request 22. If no status page should be sent then the NO branch of decisional step 350 is followed to decisional step 352. If the delay before the prioritized request is handled is below the predetermined time period then the NO branch of decisional step 348 is followed to step 352.

At decisional step 352, flow control server 34 determines whether origin server 18 is still at full processing capacity. If origin server 18 is not at full capacity then the NO branch of decisional step 352 is followed to step 326 where the highest priority request in the priority queue is communicated to origin server 18 for handling. If origin server 18 is at capacity, for example because origin server 18 is handling content requests previously communicated to origin server 18, then the YES branch of decisional step 352 is followed to step 354. Αt step 354, flow control server 34 waits predetermined period of time before returning to step 352 and

10

20

25

30

determining whether origin server 18 is still at capacity. For example, flow control server 34 may wait 100 milliseconds before determining whether origin server 18 has dropped below capacity.

System 10 provides numerous capabilities for improving web server performance and reliability. System 10 provides the capability to dynamically expire content for fine grained control of whether cached data is valid or invalid. at a data store, such as data source 20, can be quickly detected and the cached data from the data store expired so that out-of-date information is not provided to a user. administrator associated with a web site, such as origin server 18, can now determine in real-time when cached content should be expired. In contrast, administrators traditionally had to determine when content should be expired when the user initially retrieves the content from the web server because traditional expiration times were fixed and provided as part of the content. Because the administrator could not provide for unexpected changes in the content, such flight schedule being cancelled, flight in a administrators often used extremely short expiration times to ensure that current data is provided to users. The short expiration times cause unnecessary increased load on the servers at the web site because content could only be cached for short periods of time before being re-retrieved from the web site, even though the cached data might still be correct.

Also, system 10 provides the ability to cache both static and dynamic content. By caching both static and dynamic content remotely from a web site, the processing and network load on the web site is decreased. The processing load is decreased because the web site no longer has to generate multiple instances of dynamic data. The network load is

20

25

30

decreased because many requests for content can be handled by a data center, such as data center 14, where the content is cached instead of using the web site, such as origin server 18, to handle the requests. Caching of both static and dynamic data allows a web site to off-load the handling and providing of not only simple static content, but many items of both static and dynamic content.

Further, system 10 provides the capability to cache portions of dynamic content and configurably determine which portions to cache based on instructions from an administrator associated with a web site. This capability greatly increases the type and variety of dynamic content which can be cached by system 10. This capability also increases the effectiveness of the caching performed by system 10 because system 10 can filter the requests. Filtering requests allows system 10 to determine that distinct requests with differing content requests are actually requesting already cached content. This decreases the load experienced by the web site.

In addition, system 10 can control the load experienced by a web site, such as origin server 18, by prioritizing and controlling the flow of requests to the web site. An administrator associated with the web site can request that system 10 not allow the processing and network load to exceed certain thresholds. Thus, the administrator can now make various assumptions about the volume and frequency of requests that will be experienced by a server associated with the web site and plan accordingly. Also, by prioritizing the requests, the delay experienced by a user who is requesting content from a busy web site can be tailored by the administrator to provide appropriate service to the users of the administrator's web site.

15

Also, system 10 allows a particular site, such as origin server 18, to purchase sufficient bandwidth and processing capability to handle the normal expected load on the site, while system 10 handles the spikes in load on the site. This provides numerous cost savings to the site because the site does not need to purchase and maintain large amounts of processing capability and bandwidth that sit around unused except during the heaviest traffic.

It should also be recognized that direct connections disclosed herein could be altered such that two disclosed components or elements would be coupled to one another through an intermediate device or devices without being directly connected, while still realizing the present invention. Other changes, substitutions and alterations are also possible without departing from the spirit and scope of the present invention, as defined by the following claims.

20

5

WHAT IS CLAIMED IS:

A method for data processing comprising:

receiving a data request at a data center;

assigning a priority to the request;

queuing the request as a function of the priority associated with the request; and

retrieving the requested data from an origin server.

- The method for data processing according to Claim 1,
 wherein the data center comprises a cache server, a flow control server and a web server.
 - 3. The method for data processing according to Claim 1 further comprising:

determining a load associated with the origin server;

controlling at a flow control server retrieval of data from the origin server by a cache server;

granting permission from the flow control server to the cache server to retrieve data when the load associated with the origin server is below a threshold; and

denying permission from the flow control server to the cache server to retrieve data when the load associated with the origin server is above the threshold.

- 4. The method for data processing according to Claim 3, wherein the threshold is determined as a function of the load of the origin server.
- 5. The method for data processing according to Claim 1, wherein assigning the priority to the request comprises determining the priority based on a state associated with the request.

25

30

- 6. The method for data processing according to Claim 1 further comprising communicating alternate content to a remote computer associated with the request.
- 7. The method for data processing according to Claim 6, wherein the alternate content comprises a status page and wherein the status page is communicated when the load at the origin server exceeds a predetermined threshold.
- 10 8. The method for data processing according to Claim 6, wherein communicating the alternate content comprises:

associating a queue delay time with the request;

determining whether the queue delay time exceeds a threshold;

generating the alternate content as a function of predetermined criteria associated with the origin server when the queue delay time exceeds the threshold; and

returning the alternate content to the remote computer.

- 9. The method for data processing according to Claim 8, wherein the data requested is generated at a client computer remote from the data center and wherein generating the alternate content comprises selecting the alternate content as a function of the bandwidth available to the client computer.
 - 10. The method for data processing according to Claim 9, wherein generating the alternate content further comprises determining the amount of bandwidth available to the client computer, wherein the amount of bandwidth comprises one of high-bandwidth, medium-bandwidth and low-bandwidth.

11. The method for data processing according to Claim 8, wherein generating the alternate content further comprises generating the alternate content based on the queue delay time and the predetermined criteria.

- 12. The method for data processing according to Claim 8, wherein the predetermined criteria comprises information associated with the request.
- 13. The method for data processing according to Claim 8, wherein the predetermined criteria comprises external information associated with a user associated with the request.
- 14. The method for data processing according to Claim 13, wherein the external information comprises historical shopping information associated with the user associated with the request.
- 20 15. The method for data processing according to Claim 6, wherein the alternate content comprises a status page and further including resubmitting the data request to the data center by a browser to update the status page.
- 16. The method for data processing according to Claim 15, wherein resubmitting the data request is performed automatically by the browser.

15

- 17. The method for data processing according to Claim 1, wherein assigning the priority to the request comprises determining whether the request is prioritizable, and wherein the priority is a first priority when the request is non-prioritizable and wherein the priority is a second priority when the request is prioritizable.
- 18. The method for data processing according to Claim 17, wherein the first priority is a default priority and wherein the second priority is determined as a function of the data requested by the data request.
- 19. The method for data processing according to Claim 1 further comprising determining the load on an origin server by comparing a load metric associated with the origin server to a predetermined threshold.
- 20. The method for data processing according to Claim 19, wherein the load metric comprises the number of requests 20 being handled by the origin server.
 - 21. The method for data processing according to Claim 19, wherein the load metric comprises the number of network connections being supported by the origin server.
 - 22. The method for data processing according to Claim 19, wherein the load metric comprises the delay associated with retrieving a predetermined web page from the origin server.

30

10

15

23. The method for data processing according to Claim 1, wherein the request is a first request and wherein queuing the request comprises:

storing the first request in a queue associated with the data center, the queue having therein a plurality of second requests distinct from the first request, each of the second requests having a respective priority associated therewith;

sorting the queue as a function of the respective priority associated with the first request and each of the second requests; and

wherein retrieving the requested data comprises:

processing the highest priority request in the queue by the origin server.

24. The method for data processing according to Claim 1, wherein the data center comprises a plurality of data centers and wherein receiving the request comprises:

determining a network distance between a client computer and at least one of the data centers;

20 determining the closest data center to the client computer;

resolving a destination address associated with the request to the closest data center; and

routing the request to the closest data center.

- 25. A system for dynamic flow control comprising:
- a cache server operable to receive a request for content and retrieve content from an origin server in response thereto; and
- a flow control server having an associated queue and coupled to the cache server, the flow control server operable to:

assign a priority to the request;

store the prioritized request in the queue as a function of the priority associated with the request; and

regulate the retrieval of content from the origin server by the cache server.

- 26. The system for dynamic flow control according to Claim 25, wherein the cache server is further operable to request permission from the flow control server to retrieve content from the origin server.
- 27. The system for dynamic flow control according to Claim 25, wherein the flow control server is further operable to associate a priority with the request based on the content requested by the request and determine a processing load associated with the origin server.
- 28. The system for dynamic flow control according to Claim 25, wherein the flow control server is further operable to associated a priority with the request based on external information associated with the request.

٠.

29. The system for dynamic flow control according to Claim 28, wherein the external information comprises historical information associated with a user associated with the request.

- 30. A method for dynamic flow control comprising: receiving a data request at a flow control server; associating a priority with the data request;
- storing the data request in a queue as a function of the priority associated with the data request; and

retrieving data requested by the data request from a protected resource.

- 21. The method for dynamic flow control according to Claim 30 further comprising determining a load at the protected resource, and wherein associating a priority with the data request comprises associating the priority with the data request when the load at the protected resource exceeds a predetermined threshold and wherein queuing the data request comprises queuing the data request when the load at the protected resource exceeds the predetermined threshold.
- 32. The method for dynamic flow control according to Claim 31 further comprising indicating status information to 20 be returned to a remote computer associated with the data request.
- 33. The method for dynamic flow control according to Claim 31 further comprising indicating alternate content to be returned to a remote computer associated with the data request.
- 34. The method for dynamic flow control according to Claim 33 further comprising determining the alternate content as a function of the bandwidth associated with the remote computer.

oosooles osoole

- 35. The method for dynamic flow control according to Claim 32, wherein the status information comprises a status web page and wherein indicating status information comprises selecting the status page based on priority criteria associated with the protected resource.
- 36. The method for dynamic flow control according to Claim 35 further comprising resubmitting the data request after a predetermined time interval to the flow control server.
- 37. The method for dynamic flow control according to Claim 36, wherein resubmitting the data request is performed automatically.

15

10

5

38. The method for dynamic flow control according to Claim 35 further comprising delaying communication of the status page indication for a predetermined time interval based on the priority criteria.

20

- 39. The method for dynamic flow control according to Claim 38, wherein delaying communication of the status page comprises delaying communication of the status page indication based on an expected delay associated with the protected resource.
- 40. The method for dynamic flow control according to Claim 31, wherein receiving the data request comprises receiving the data request from a flow controlled device.

30

10

20

41. The method for dynamic flow control according to Claim 31, wherein retrieving the data requested by the data request comprises:

removing at least one prioritized data request from the queue when the load at the protected resource is below the predetermined threshold;

communicating the prioritized data requests to the protected resource;

retrieving the requested data from the protected resource; and

communicating the requested data to a flow controlled device associated with the data request.

- 42. The method for dynamic flow control according to 15 Claim 41, wherein removing at least one prioritized data request comprises removing the highest priority data request.
 - 43. The method for dynamic flow control according to Claim 41, wherein associating the priority with the request comprises determining whether the request is prioritizable, and wherein the priority is a first priority when the request is non-prioritizable and wherein the priority is a second priority when the request is prioritizable.
- 44. The method for data processing according to Claim 43, wherein the first priority is a default priority and wherein the second priority is determined as a function of the request.

10

25

45. A method for content filtering comprising:

receiving a data request at a flow control server from a flow controlled device, the data request having associated requested data;

evaluating the requested data against criteria;

discarding the data request when the requested data is forbidden by the criteria;

determining alternate data based on the criteria and the requested data when the requested data is forbidden by the criteria; and

indicating the alternate data to the flow controlled device when the requested data is forbidden.

- 46. The method of content filtering according to Claim 15 45, wherein the criteria comprises the geographic origin of the data request.
- 47. The method of content filtering according to Claim 45, wherein the criteria comprises the content of the 20 requested data.
 - 48. The method of content filtering according to Claim 45, wherein the criteria comprises the geographic origin of the data request and the content of the requested data.
 - 49. The method of content filtering according to Claim 45, wherein the alternate data comprises a content forbidden web page.
- 30 50. The method of content filtering according to Claim 45, wherein the alternate data comprises an allowable web page.

- 51. The method of content filtering according to Claim 45, wherein indicating the alternate data comprises returning the alternate data to the flow controlled device.
- 5 52. The method of content filtering according to Claim 45, wherein indicating the alternate data comprises returning a location of the alternate data to the flow controlled device.

15

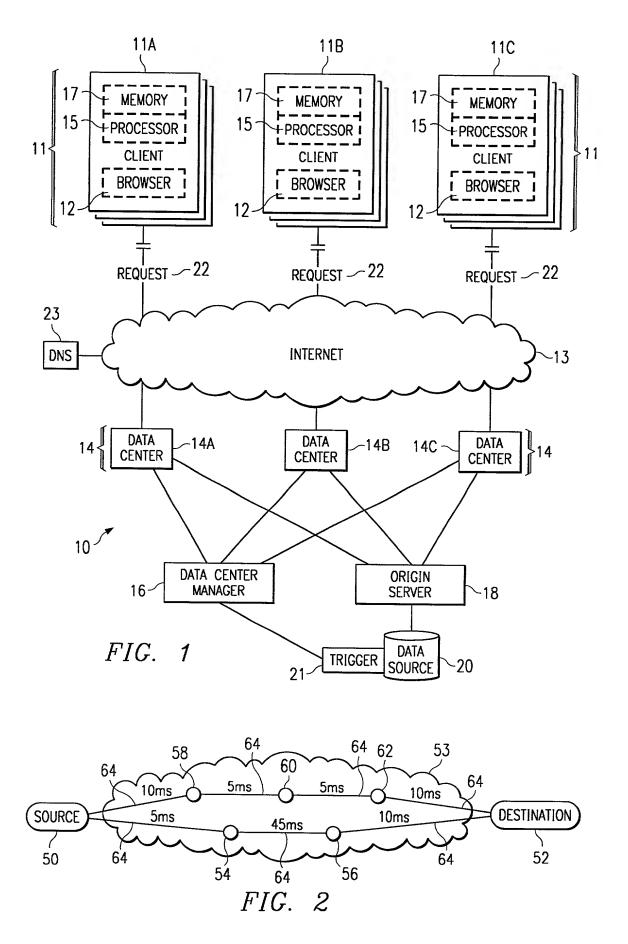

20

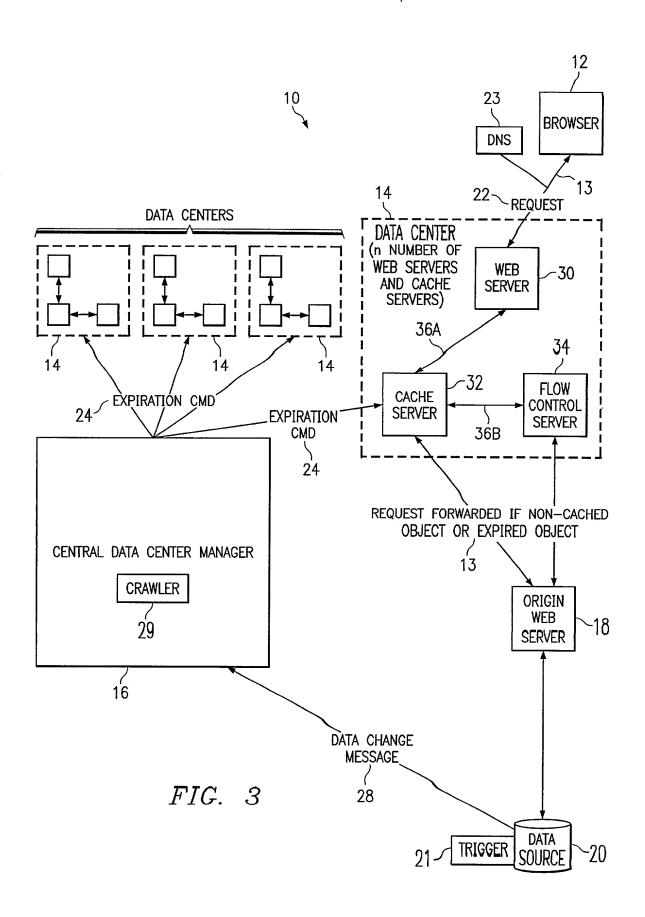

METHOD AND APPARATUS FOR DYNAMIC DATA FLOW CONTROL

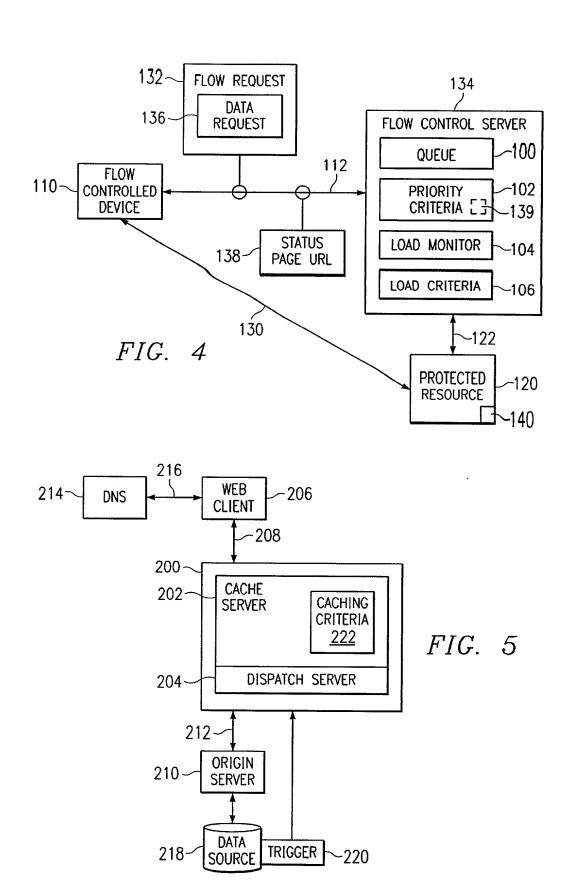

ABSTRACT OF THE DISCLOSURE

A data center (14) receives a request (22) for content from a browser (12) on a client (11). The data center determines whether the requested content is available at the The content is available when the content is data center. both present at the data center and current. The content may be expired and marked as non-available in response to expiration command (24). When the requested content available at the data center, the data center returns the requested content to the data center. When the requested content is locally unavailable at the data center, requested content is retrieved from an origin server (18). The retrieval of the content from the origin server may be delayed based on the processing load at the origin server. When retrieval of the content is delayed, the request is prioritized and placed in a queue for handling by the origin server based on the priority of the request. Also, when retrieval of the content is delayed, a status page may be communicated to the browser to inform a user of the delay and provide alternate content (139) and status information related to the request determined as a function of the request or the current state of the origin server.

DECLARATION AND POWER OF ATTORNEY

As a below named inventor, I declare that:

My residence, post office address and citizenship are as stated below next to my name, that I believe I am the original, first and joint inventor of the subject matter which is claimed and for which a patent is sought on the invention or design entitled *METHOD AND APPARATUS FOR DYNAMIC DATA FLOW CONTROL*, the specification of which is attached hereto;

That I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above; and

That I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me to be material to patentability as defined in 37 C.F.R. § 1.56.

I hereby claim foreign priority benefits under 35 U.S.C. § 119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application(s) for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Claimed		Date	Priority
<u>Number</u>	Country	<u>Filed</u>	(Yes) (No)
		- 11-	
		-NONE	

I hereby claim the benefit under 35 U.S.C. § 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application(s) in the manner provided by the first paragraph of 35 U.S.C. § 112, I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me to be material to patentability as defined in 37 C.F.R. § 1.56 which became available between the filing date of the prior application(s) and the national or PCT international filing date of this application:

	NONE	
Application Serial Number	_Date Filed	Status

I hereby claim the benefit under Title 35, United States Code, § 119(e) of any United States provisional application(s) listed below:

(Application No.) I hereby appoint: Jerry W. Mills Robert M. Chiaviello, Jr. Ann C. Livingston Reg. No. 32,461 Reg. No. 32,479 Thomas R. Felger Charles S. Fish Reg. No. 35,870 Revin J. Meek Reg.
